1 The conjecture

The Online Encyclopedia of Integer Sequences records [A246475](#) as

Number of length $n+3$ 0..4 arrays with no pair in any consecutive four terms totalling exactly 4

and carries in its Formula section the lines:

Empirical: $a(n) = 2a(n-1) + a(n-3) + 14a(n-4) + 3a(n-5) + 6a(n-6) + a(n-8) + a(n-9).$

Empirical g.f.: $4x(43 + 35x + 102x^2 + 245x^3 + 80x^4 + 99x^5 + 7x^6 + 21x^7 + 16x^8) / (1 - 2x - x^3 - 14x^4 - 3x^5 - 6x^6 - x^8 - x^9).$ - Colin Barker, Nov 06 2018

That line carries no separate signature; the entry itself is by R. H. Hardin (Aug 27 2014).

The line quoted ending in that signature is contributed by Colin Barker on Nov 06 2018.

The word *Empirical* — equivalently *Conjecture* — is the entry's own: the statement is recorded as fitted to the published terms, and no proof is given there. As of revision 7, last modified Nov 06 2018, the entry records no proof and links to none, so the statement is open. This note settles it.

Written out, the claim is

$$a(n) = 2a(n-1) + a(n-3) + 14a(n-4) + 3a(n-5) + 6a(n-6) + a(n-8) + a(n-9).$$

stated without a range; it first has meaning at $n = 10$, the least index at which all of $a(n-1), \dots, a(n-9)$ are terms of the sequence.

Written out, the claim is

$$\sum_{n \geq 1} a(n) x^n = \frac{172x + 140x^2 + 408x^3 + 980x^4 + 320x^5 + 396x^6 + 28x^7 + 84x^8 + 64x^9}{1 - 2x - x^3 - 14x^4 - 3x^5 - 6x^6 - x^8 - x^9}.$$

2 The object

The name is read as follows. The reading is not a guess: it is pinned against the entry's own published terms, and against an independent enumeration, before anything is proved (Section 7).

The objects are the words $w_1 w_2 \cdots w_L$ over $\{0, 1, \dots, 4\}$ of length $L = n + 3$ satisfying the entry's conditions, which are, clause by clause:

- *no pair in any consecutive four terms totalling exactly 4*

Each of these is a condition on a window of consecutive terms of bounded width, except the labelling clause where present, which says that the first occurrences of the values happen in increasing order.

$a(n)$ is the number of such arrays. The entry's offset is 1, so its term of index n is the count for n rows.

3 The count is a walk count

Read the word one letter at a time. Every condition is decided by a window of at most a fixed number of consecutive letters, so it becomes checkable as soon as that many letters have been read; and the labelling clause, where the entry has one, is decided by how many distinct values have been introduced so far, a number between 0 and 5.

Take as state the last few letters together with that counter. Appending a letter is a transition; a word of length L is a walk of length L from the empty state, and every word arises from exactly one walk. With M the adjacency matrix of the state digraph, w the indicator of the start and f of the accepting states, $a(n) = w^\top M^L f$, so the count is C-finite.

4 The degree bound, derived

The reachable part of that digraph has 156 states, 156 after trimming. Identifying states with the same number of completions of every length, and then the mirror identification on the edges coming in, leaves $S = 17$ blocks. The count satisfies the linear recurrence given by the characteristic polynomial of the 17×17 quotient matrix; that degree bound is computed here, not assumed.

5 The decision procedure

Let $c_1, \dots, c_D$ be the coefficients of a claimed recurrence $a(n) = \sum_{i=1}^D c_i a(n-i)$, let $q(t) = t^D - \sum_{i=1}^D c_i t^{D-i}$ be its characteristic polynomial, and put

$$u_m = \tilde{w}^\top L^{m-1} q(L) \tilde{f} \quad (m \geq 1).$$

Expanding the powers of L and using the displayed formula for a , one gets $u_m = a(n) - \sum_{i=1}^D c_i a(n-i)$ with $n = m + D$. So u_m is exactly the residual of the claim at that index, and the recurrence holds at an index n if and only if the corresponding u_m vanishes.

Now $u_m = \tilde{w}^\top L^{m-1} y$ with $y = q(L)\tilde{f}$ a fixed vector, so (u_m) satisfies the characteristic polynomial of L , of degree 17: writing that polynomial as $t^{17} - \sum_{i=1}^{17} \lambda_i t^{17-i}$ gives $u_{m+17} = \sum_{i=1}^{17} \lambda_i u_{m+17-i}$. Hence 17 consecutive vanishing residuals force every later residual to vanish, by induction. The test is therefore finite; and because it locates the *last* nonvanishing residual, it pins the threshold exactly rather than merely bounding it.

Everything is carried out in exact integer arithmetic on the vector $L^{m-1}y$. The matrix M is never formed.

6 Results

Theorem 1. *For A246475, the recurrence $a(n) = 2a(n-1) + a(n-3) + 14a(n-4) + 3a(n-5) + 6a(n-6) + a(n-8) + a(n-9)$ holds for every $n \geq 10$ — at every index at which it can be stated.*

Proof. The residuals u_m were computed exactly for $m = 1, \dots, 55$. Every one of them vanished. After it, more than $S = 17$ consecutive residuals vanish, so by Section 5 every later residual vanishes as well. $\square$

Theorem 2. *For A246475, the generating function is exactly $\sum_{n \geq 1} a(n)x^n =
